

# Contrail Avoidance: What are the issues from a climate science (or, at least, my) perspective?

Keith P Shine

Department of Meteorology, University of Reading

[k.p.shine@reading.ac.uk](mailto:k.p.shine@reading.ac.uk)

Aviation Reimagined: October 2024

Thanks historically to many colleagues at Reading (especially Emma Klingaman (née Irvine)) and beyond. – they don't (all) necessarily share my views

## Some key questions

1. Can contrails be avoided? **YES**, and we've known how to for about 70 years!
2. Most importantly: can they be avoided now in a way
  - (a) that the potential climate benefit can be reliably quantified?  
**NO**
  - (b) that we can guarantee perverse outcomes (i.e., *greater* climate change) are avoided? **NO**
4. Might it be possible sometime in the future? **YES – it can be demonstrated in a “perfect model” environment where we know exactly where contrails will form and have a robust knowledge of their properties**

## Understanding the role of contrails and contrail cirrus in climate change: a global perspective

Dharmendra Kumar Singh, Swarnali Sanyal, and Donald J. Wuebbles

Department of Climate, Meteorology & Atmospheric Sciences (CliMAS), University of Illinois Urbana-Champaign, Urbana, IL 61801, USA

Very active research area – just a few recent (2024) papers

# Mitigation of aviation's climate impact by contrail avoidance: What could possibly go wrong?

## Multiple uncertainties

- Can we reliably predict (persistent) contrail formation?
- Can we reliably predict contrail properties over their lifetime?
- Can we reliably predict contrail *radiative* properties over their lifetime?
- Can we reliably predict the *climate* impact of the contrails?
- Do we know how best to compare CO<sub>2</sub> and non-CO<sub>2</sub> climate impacts?

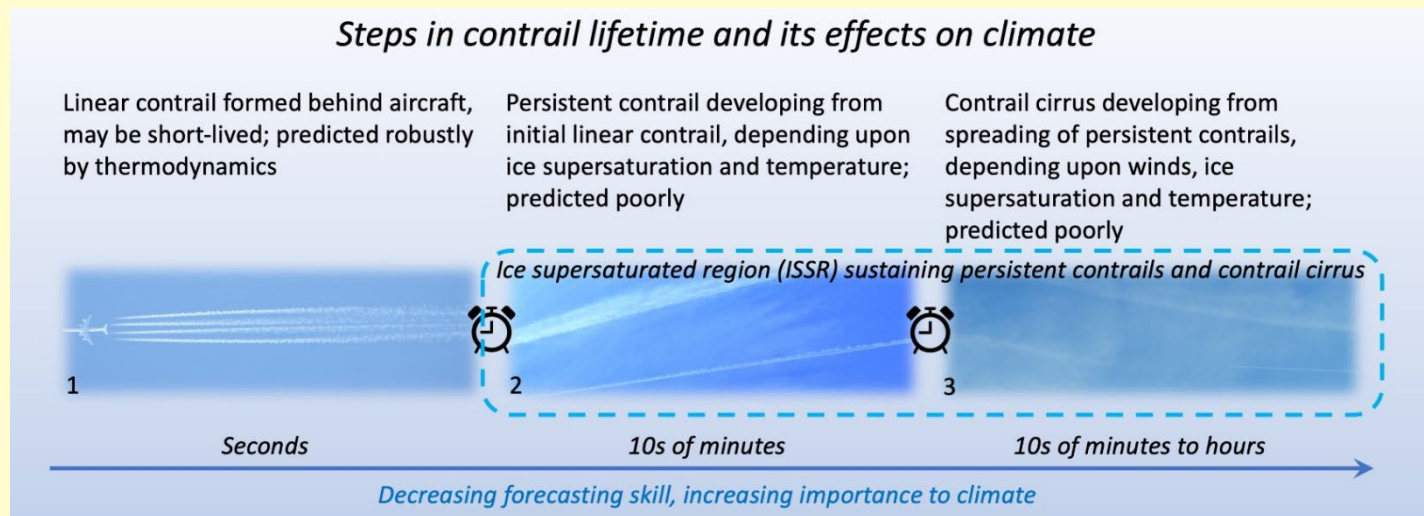

# Mitigation of aviation's climate impact by contrail avoidance: What could possibly go wrong?

## Multiple uncertainties

- Can we reliably predict (persistent) contrail formation?
- Can we reliably predict contrail properties over their lifetime?
- Can we reliably predict contrail *radiative* properties over their lifetime?
- Can we reliably predict the *climate* impact of the contrails?
- Do we know how best to compare CO<sub>2</sub> and non-CO<sub>2</sub> climate impacts?

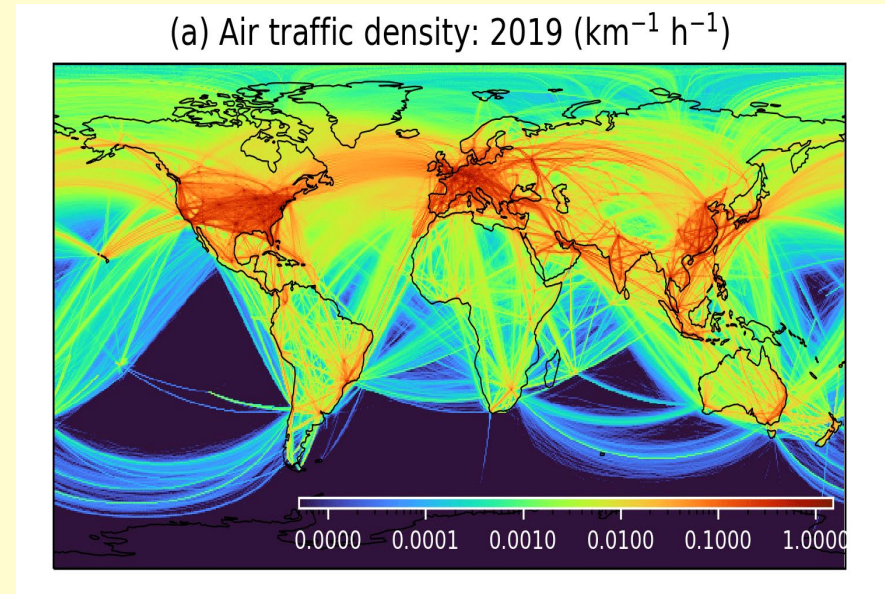

# Some contrail basics

- Contrails are “mixing clouds” much like seeing breath on a cold day. Unsaturated air parcels mix and can saturate
- Normally that cloud dissipates quickly as the contrail mixes with more surrounding air
- In the upper troposphere, the surrounding air *can* be “supersaturated with respect to ice” (ISSRs)
- The supersaturated air can condense on the frozen droplets forming *persistent* contrails; these can spread to form *contrail cirrus*.

# ISSRs frequency; co-location with air traffic determines contrail cirrus distributions

Ice supersaturation occurrence frequencies (from aircraft-calibrated satellite retrievals)

Lamquin et al. 2012 10.5194/acp-12-381-2012

Teoh et al. 2024

10.5194/acp-24-725-2024

ISSRs are patchy in time and in the vertical and horizontal; they are determined by the prevailing weather conditions

# Sometimes persistent, sometimes not

# Outcomes of 2021 Maastricht Contrail Avoidance Trial

- Pioneering study of Sausen et al. 2023 (10.1127/metz/2023/1157) where “real-time” decisions were made on whether aircraft could be rerouted based on weather forecasts
- My interpretation of their results
- On 55% of occasions, contrails were predicted but not observed
- On occasions when contrails were either predicted or occurred, the forecast was right only 36% of the time

Cases (3398) where no avoidance action was taken		Persistent Contrails Predicted	
		Yes	No
Persistent Contrails Observed	Yes	442	248
	No	543	2165

Wilhelm, L.; Gierens, K.; Rohs, S. (2022) *Appl. Sci.* 12. 10.3390/app12094450

*“unreliable prediction of relative humidities is one reason why contrail prediction is not possible for flight routing”*

Hofer, S.; Gierens, K and Rohs, S. (2024) 10.5194/acp-24-7911-2024

*“the prediction of contrail persistence [is] very difficult”*

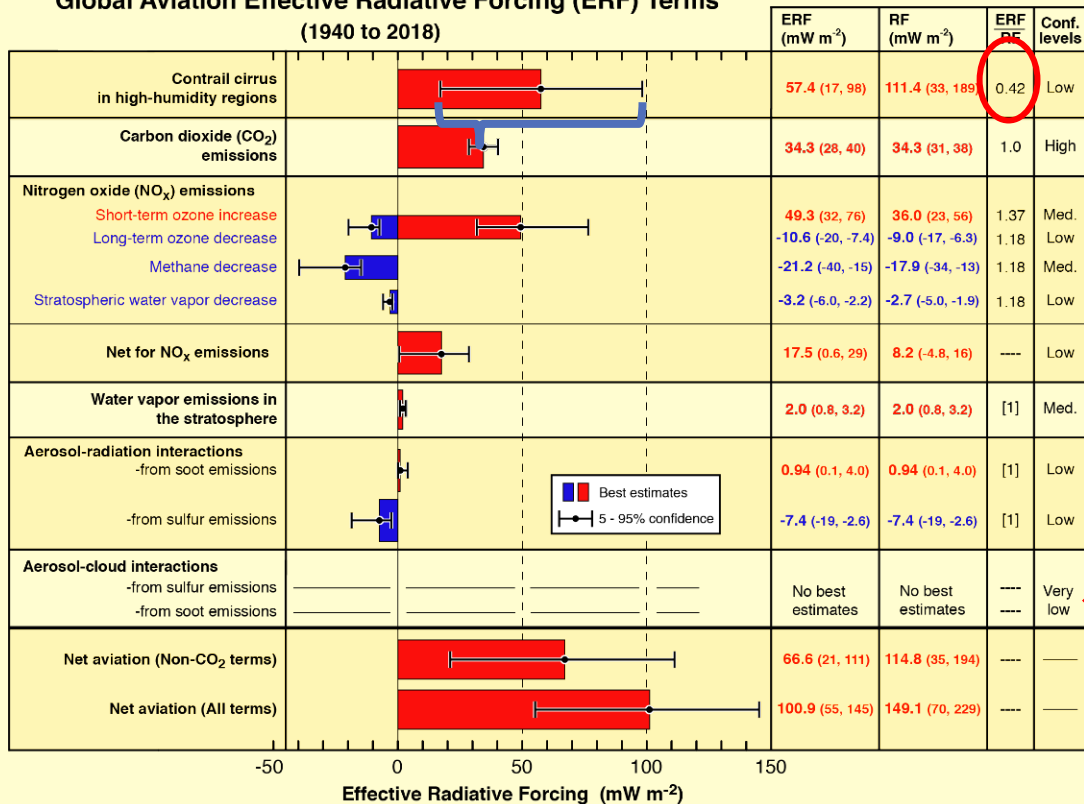

# Mitigation of aviation's climate impact by contrail avoidance: What could possibly go wrong?

## Multiple uncertainties

- Can we reliably predict (persistent) contrail formation?
- Can we reliably predict contrail properties over their lifetime?
- Can we reliably predict contrail *radiative* forcing over their lifetime?
- Can we reliably predict the *climate* impact of the contrails?
- Do we know how best to compare CO<sub>2</sub> and non-CO<sub>2</sub> climate impacts?

# Radiative Forcing due to Aviation

Global Aviation Effective Radiative Forcing (ERF) Terms  
(1940 to 2018)

Contrail uncertainty is huge! Could be anything between  $\approx 0.5$  and  $\approx 3x$  that of CO<sub>2</sub>

Other non-CO<sub>2</sub> aviation forcings depend on the “where and when” of emissions

Some of this *highly uncertain* forcing may originate from processing of soot particles in contrails. Size and sign remains poorly constrained

Aviation CO<sub>2</sub> RF (about 35 mW m<sup>-2</sup>) causes about 1.5% of the total effect of CO<sub>2</sub> from human activities

When non-CO<sub>2</sub> effects are included, aviation contributes 1.3 to 14% of the total climate effect of human activities (neglecting any aerosol-cloud forcing)

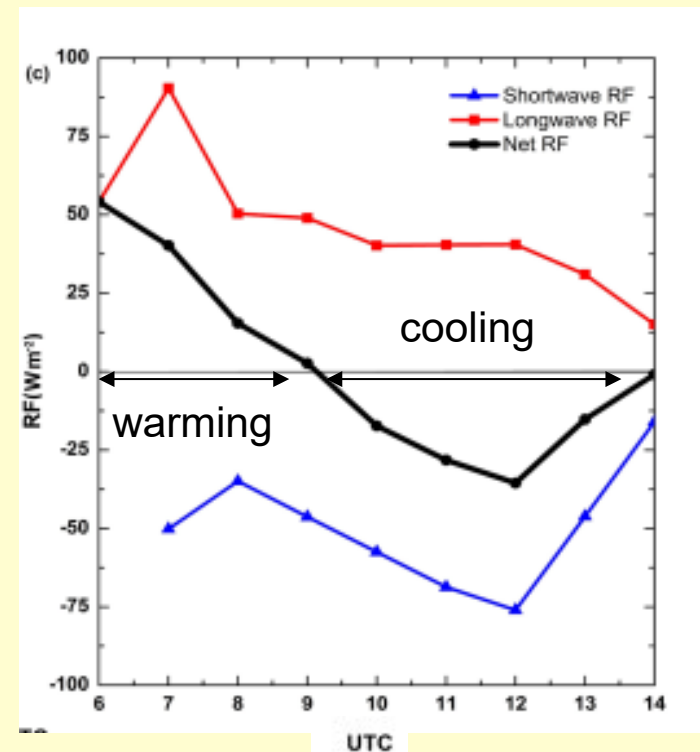

# Contrail case studies – compensation between (modelled) longwave and shortwave forcing

## Key points

1. The net forcing is a relatively small residual of shortwave (“solar”) forcing and longwave (“infrared”) forcing; the **sign** of the net forcing can vary
2. This net forcing **evolves** during the contrail-cirrus lifetime; it needs to be tracked as it moves with the wind, as insolation changes, and as cloud properties change

## Observations of microphysical properties and radiative effects of a contrail cirrus outbreak over the North Atlantic

Ziming Wang<sup>1,2</sup>, Luca Bugliaro<sup>1</sup>, Tina Jurkat-Witschas<sup>1</sup>, Romy Heller<sup>1</sup>, Ulrike Burkhardt<sup>1</sup>, Helmut Ziereis<sup>1</sup>, Georgios Dekoutsidis<sup>1</sup>, Martin Wirth<sup>1</sup>, Silke Groß<sup>1</sup>, Simon Kirschler<sup>1,3</sup>, Stefan Kaufmann<sup>1</sup>, and Christiane Voigt<sup>1,3</sup>

# Radiative Forcing is a proxy for climate change

**RADIATIVE FORCING (RF):** The change in top-of-atmosphere energy budget due to e.g., contrails, in absence of (almost) any other change

Most contrail-climate studies calculate this

**EFFECTIVE RADIATIVE FORCING (ERF):** RF plus any “rapid adjustments” - atmospheric changes (e.g., cloudiness, humidity) that occur in absence of any surface temperature change.

IPCC’s preferred forcing definition. Adjustments need to be calculated using Earth System Models - **very few studies** for contrails. All indicate ERF/RF between 0.31 and 0.65 - see Lee et al. (2021) assessment and Bickel DLR PhD thesis.

Global Aviation Effective Radiative Forcing (ERF) Terms  
(1940 to 2018)

	ERF (mW m <sup>-2</sup> )	RF (mW m <sup>-2</sup> )	ERF RF	Conf. levels
Contrail cirrus in high-humidity regions	57.4 (17, 98)	111.4 (33, 189)	0.42	Low

Contrails occur at the “expense” of natural cirrus clouds

# Understanding of contrail RF is still evolving

Global Aviation Effective Radiative Forcing (ERF) Terms  
(1940 to 2018)

	ERF (mW m <sup>-2</sup> )	RF (mW m <sup>-2</sup> )	ERF RF	Conf. levels
Contrail cirrus in high-humidity regions	57.4 (17, 98)	111.4 (33, 189)	0.42	Low

Since Lee et al. (2021) e.g.,

- Zhang et al. (2024): “contrail cirrus ERF of the year 2018 to be 41 mW m<sup>-2</sup> in the UM and 60 mW m<sup>-2</sup> in CAM ...[and] find a factor of 8 uncertainty ... due to existing uncertainty in contrail cirrus optical depth

Since Lee et al. (2021) e.g.,

- Bier and Burkhardt (2022): parameterizing microphysical processes in the jet and vortex phase: “Global mean RF is **44** mW m<sup>-2</sup> ... 22% lower than ... (our) previous study”
- Teoh et al. (2024) “we estimate that the 2019 global contrail net RF could range between **34.8** and **74.8** mW m<sup>-2</sup>”
- Quaas et al. (2021) ... satellite observations of COVID impact “... translates to a global RF of **61** ± 39 mW m<sup>-2</sup>.”

All are lower than the Lee et al. best estimate

# Mitigation of aviation's climate impact by contrail avoidance: What could possibly go wrong?

## Multiple uncertainties

- Can we reliably predict (persistent) contrail formation?
- Can we reliably predict contrail properties over their lifetime?
- Can we reliably predict contrail *radiative* properties over their lifetime?
- Can we reliably predict the *climate* impact of the contrails?
- Do we know how best to compare CO<sub>2</sub> and non-CO<sub>2</sub> climate impacts?

# Radiative Forcing is only a proxy for climate change!

RADIATIVE FORCING (RF):

EFFECTIVE RADIATIVE FORCING (ERF):

SURFACE TEMPERATURE CHANGE  $\Delta T_s$ : impact of ERF on surface temperature, including climate feedbacks driven by this surface temperature change

Equilibrium surface temperature response

$$\Delta T_s \approx \lambda RF$$

$\lambda$  is climate sensitivity in K (W m<sup>-2</sup>)<sup>-1</sup>

$\lambda$  is a chronic climate science uncertainty, that also depends on the nature of the radiative forcing (Ponater et al., 2021). Only one contrail calculation ... so far.

Bickel's results indicate contrails *may* have **much reduced** efficacy (about 0.4 of  $\lambda_{CO_2}$ ) due to distinct cloud feedbacks

This reduction acts **in addition** to the ERF/RF reduction

# Simple illustration of how perspective of contrail importance can change

RF  $\Rightarrow$  ERF  $\Rightarrow$  Surface temperature

- Based on ERF and efficacy computed in a single ESM

Bickel [10.57676/mzmg-r403](https://doi.org/10.57676/mzmg-r403)

# Mitigation of aviation's climate impact by contrail avoidance: What could possibly go wrong?

## Multiple uncertainties

- Can we reliably predict (persistent) contrail formation?
- Can we reliably predict contrail properties over their lifetime?
- Can we reliably predict contrail *radiative* properties over their lifetime?
- Can we reliably predict the *climate* impact of the contrails?
- Do we know how best to compare CO<sub>2</sub> and non-CO<sub>2</sub> climate impacts?

# Contrail avoidance – potential outcomes

**1. Successful re-route** (but only if extra fuel use is justified to avoid contrail)<sup>1</sup>. Persistent contrail conditions occur where predicted, spreading into contrail cirrus.

<sup>1</sup>Assuming it can be verified that persistent contrail conditions would have occurred, as predicted, on original route

Lee et al. (2023) *Env.Sci:Atmospheres* 10.1039/d3ea00091e

Accepting that minimum *fuel* routes are not necessarily minimum *cost* routes, and several alternative minimum fuel routes may be present on a given day ...

# Comparing contrail climate effects with CO<sub>2</sub>

The long persistence time of CO<sub>2</sub> – one of its most troublesome aspects

Pulse of CO<sub>2</sub> (100 PgC) emitted at time zero

A contrail (with a hugely exaggerated lifetime!)

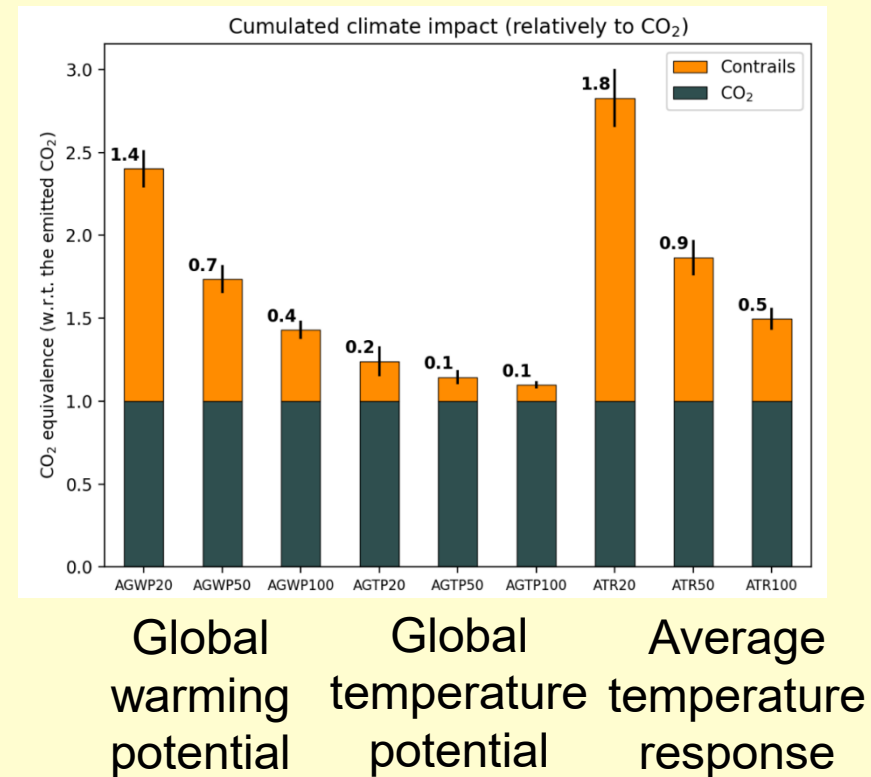

IPCC AR5 WG1 (2013) Box 6.1 Figure 1

# Metric and efficacy uncertainties

Recent study by Borella et al. 2024 ACP  
CO<sub>2</sub> equivalence of North Atlantic flights  
in 2019 depends on metric choice and  
time horizon choice

(Uncertainties in contrail forcing and  
efficacy not represented here)

The metric should match the policy aim

10.5194/acp-24-9401-2024

See also:

<https://doi.org/10.1038/s43247-024-01423-6>  
**Alternative climate metrics to the Global Warming Potential are more suitable for assessing aviation non-CO<sub>2</sub> effects**

Check for updates

Liam Megill<sup>1,2</sup>, Kathrin Deck<sup>2</sup> & Volker Grewe<sup>1,2</sup>

# Concluding ... issues that need addressing

- Reliable forecasting of the occurrence of ice-supersaturated regions
- Reliable forecasting of the *degree* of ice supersaturation (which helps determine the radiative properties of contrails)
- Knowing the size of the radiative forcing of contrails (or the avoided contrail) with sufficient confidence
- Verifiable knowledge of the climate impact of the contrail (or an avoided contrail) over its entire lifetime (or avoided lifetime)
- Consensus on how to compare the climate effect of any extra CO<sub>2</sub> emissions with those of an avoided contrail

My view: the Technology Readiness Level for climate mitigation via contrail avoidance is in the “exploratory” phase (**TRL≈2** – would need to be 9 for application)

It can be demonstrated in a “perfect model” environment; we are well short of doing so in the real world

Any increase in CO<sub>2</sub> emissions as part of a mitigation strategy appears risky, when multiple uncertainty factors are at play

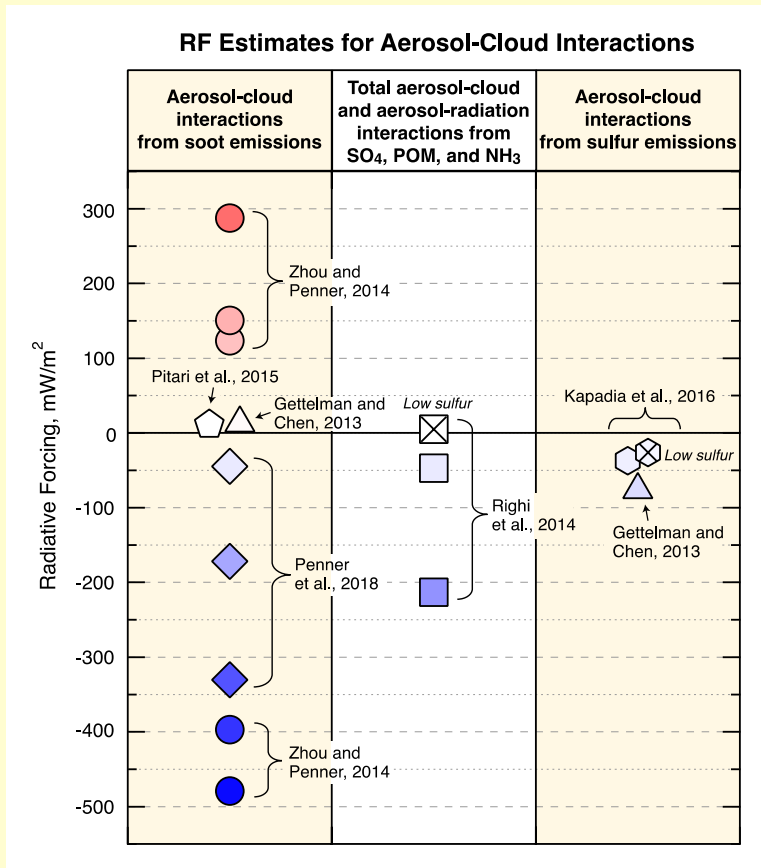

# Aerosol-cloud interactions

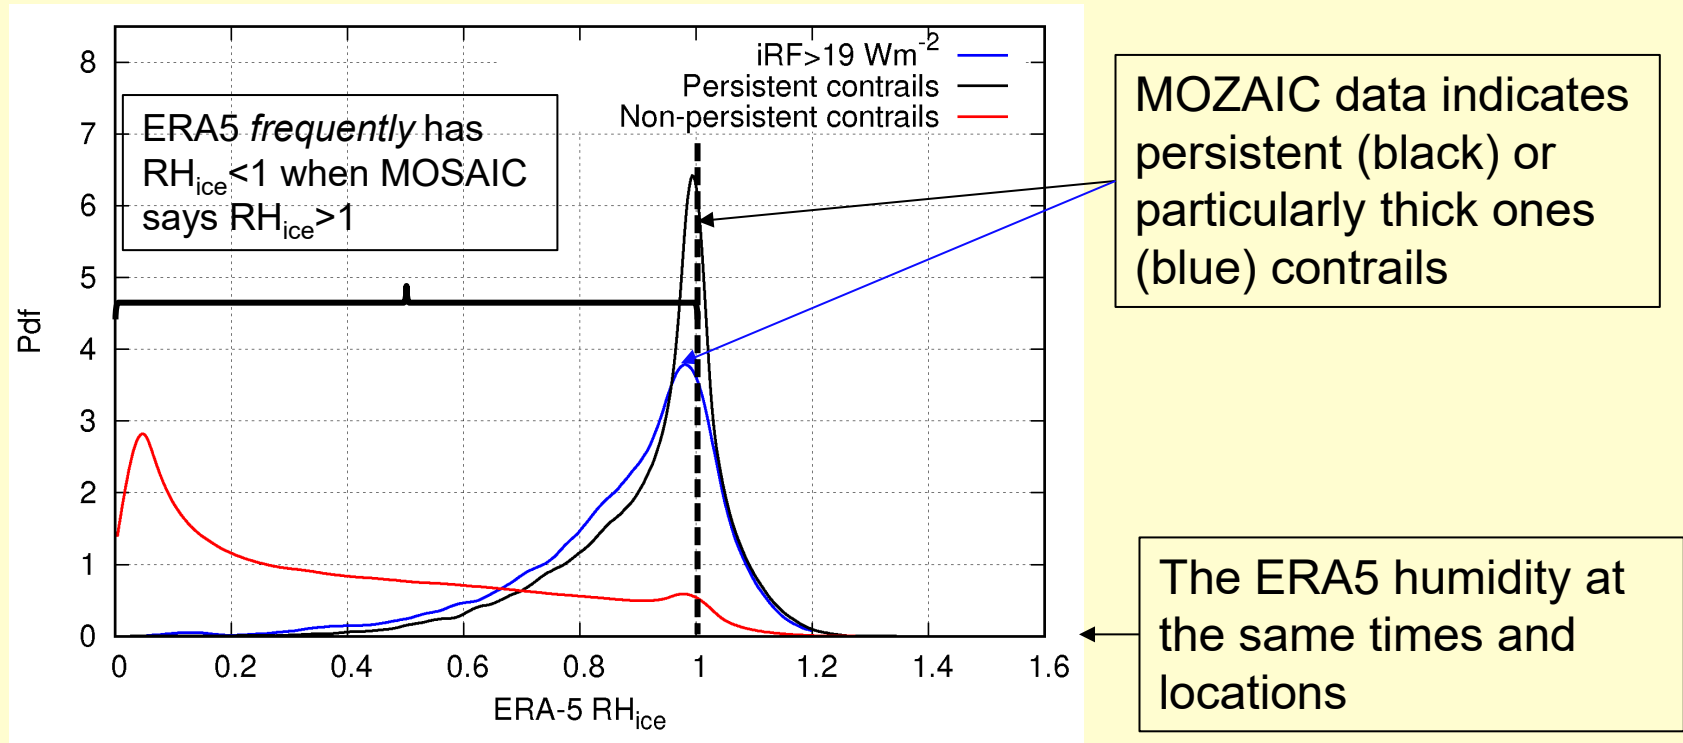

- A key uncertainty – aviation soot “processed” in contrails may affect the radiative properties of other clouds

**Key takeaway** – no best estimates are available for aerosol-cloud interactions and the net sign is unconstrained but the forcing is potentially large

# How well are ISSRs forecast?

- In-situ observations of relative humidity (IAGOS/MOZAIC) from in service aircraft (mainly Europe/N.America/N. Atlantic) with one major meteorological (“ERA5”) reanalyses (not forecasts!)

Wilhelm, L.; Gierens, K.; Rohs, S. (2022) *Appl. Sci.* 12. 10.3390/app12094450

*“unreliable prediction of relative humidities is one reason why contrail prediction is not possible for flight routing”*

Hofer, S.; Gierens, K and Rohs, S. (2024) 10.5194/acp-24-7911-2024

*“the prediction of contrail persistence [is] very difficult”*

# Ice super-saturated regions (ISSR)

ISSR layers have mean depth of  $\approx 1$  km but this is very variable and can have complex vertical structure

Relative Humidity Profiles wrt to water and ice  
Herstmonceux, UK  
12:00 on 5 May  
2016

... and very patchy on a day-to-day basis in the horizontal

ECMWF Analysis (best estimate) of ISSRs  
FL390 12:00 06 January 2016  
From Emma Irvine and Jenny Handsley

The vertical, horizontal and temporal patchiness of ISSRs is a serious issue for contrail avoidance strategies

## In a perfect-model world ...

What if we knew *exactly* where the ISSRs are, and *exactly* what radiative forcing any contrail (or avoided contrail) cause?

e.g. Case study as part of long-finished EU project ATM4E, led by Sigrun Matthes, DLR, Germany

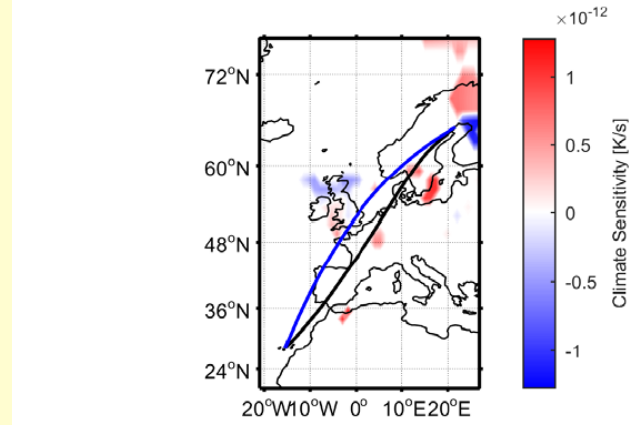

See how re-routing would change “total” climate impact

# Case Study Lulea (Finland) to Gran Canaria

Great circle route

Minimum fuel route

An ISSR patch which would cause positive contrail RF if flown through

Vertical deviation avoids most of ISSR: increases fuel use by 0.5%, reduces climate impact by 8-10% for a range of climate metrics
